

# Function Types and Higher-order Functions

**Today starts as a Paper + Pencil or Tablet + Pencil  
day... please keep laptops stowed away!**

**COMP110 - CL15**  
2024/03/26

# Warm-up: Fill in the blanks with valid function call names.

This will be today's attendance submission (CL15). Submit once complete.

```
1  def e(x: int, y: int) -> int:  
2  |     return x + y  
3  
4  
5  def f(x: int) -> int:  
6  |     return 2 * x  
7  
8  
9  def g(x: str) -> int:  
10 |    return len(x)  
11  
12  
13 def h(x: int) -> str:  
14 |    return str(x)
```

```
17 a: str = _____(110)  
18  
19  
20 b: int = _____(110)  
21  
22  
23 c: int = _____(100, 10)  
24  
25  
26 d: int = _____("110")
```

# The *Type* of a Function

# Given the following functions, write each's Callable type

```
1  def e(x: int, y: int) -> int:  
2  |    return x + y  
3  
4  
5  def f(x: int) -> int:  
6  |    return 2 * x  
7  
8  
9  def g(x: str) -> int:  
10 |    return len(x)  
11  
12  
13 def h(x: int) -> str:  
14 |    return str(x)
```

Example for e:

Callable[[int, int], int]

## #2: Diagram the Listing (in diagram, ignore the import)

```
1  from typing import Callable  
2  
3  
4  def f(x: int) -> str:  
5      |     return str(2 * x)  
6  
7  
8  g: Callable[[int], str]  
9  g = f  
10  
11 result: str = g(110)  
12 print(result)
```

# #3: Fill in the blank with all possible, valid function names:

```
4  def e(x: int) -> int:
5  |    return 2 // x
6
7
8  def f(x: int) -> str:
9  |    return str(2 * x)
10
11
12 def g(x: int) -> int:
13 |    return 2 * x
14
15
16 def h(x: int) -> int:
17 |    return 2 + x
18
19
20 a_function: Callable[[int], int] = _____
21
22 print(a_function(110))
```

# Function Writing Practice

- Start a new file in your lecture directory, add directory named cl15, create a Python module named higher\_order.py
- Write two functions:
  - A function named *square* that takes a float and returns a float, squaring it
  - A function named *map\_square* that takes a list of floats, and returns a new list of floats where each item is the result of *calling* your *square* function with the item.
- Try calling each function in the Trailhead REPL to confirm correctness

# Code Along

- Now let's try doing the same for *double* and *map\_double* functions
- Can you identify some similarities?
- Besides the name of the function, what is the only difference?
- Let's try *abstracting* this algorithm to a single function called *map* with a *Callable* parameter.

```
12  ↵ def map_square(xs: list[float]) -> list[float]:  
13      result: list[float] = []  
14  ↵      for x in xs:  
15          | result.append(square(x))  
16      return result  
17  
18  
19  ↵ def map_double(xs: list[float]) -> list[float]:  
20      result: list[float] = []  
21  ↵      for x in xs:  
22          | result.append(double(x))  
23      return result
```

# Goal

- Notice we've parameterized the function that gets called to a *Callable* parameter named *f*

## The Higher-order *map* Function Definition

```
26 def map(f: Callable[[float], float], xs: list[float]) -> list[float]:  
27     result: list[float] = []  
28     for x in xs:  
29         result.append(f(x))  
30     return result
```

Generalizes these more narrowly useful functions.

```
12 # def map_square(xs: list[float]) -> list[float]:  
13 #     result: list[float] = []  
14 #     for x in xs:  
15 #         result.append(square(x))  
16 #     return result  
17  
18  
19 # def map_double(xs: list[float]) -> list[float]:  
20 #     result: list[float] = []  
21 #     for x in xs:  
22 #         result.append(double(x))  
23 #     return result
```

Now *any* function that takes a float and returns a float can be *mapped* over a list of floats.

```
33 values: list[float] = [1.0, 5.0, 10.0]  
34 print(map(double, values)) # [2.0, 10.0, 20.0]  
35 print(map(square, values)) # [1.0, 25.0, 100.0]
```

# Diagram

```
1  from typing import Callable
2
3
4  def map(f: Callable[[float], float], xs: list[float]) -> list[float]:
5      result: list[float] = []
6      for x in xs:
7          result.append(f(x))
8      return result
9
10
11     def halve(x: float) -> float:
12         return x / 2.0
13
14
15     values: list[float] = [2.0, 4.0]
16     ys: list[float] = map(halve, values)
17     print(ys)
```

```
1 from typing import Callable
2
3
4 def map(f: Callable[[float], float], xs: list[float]) -> list[float]:
5     result: list[float] = []
6     for x in xs:
7         result.append(f(x))
8     return result
9
10
11 def halve(x: float) -> float:
12     return x / 2.0
13
14
15 values: list[float] = [2.0, 4.0]
16 ys: list[float] = map(halve, values)
17 print(ys)
```
